

SAP BDC AUTHORIZATION WIZARD

Row-Level Security, Simplified

A guided platform for building, testing, and synchronizing role-based data access in SAP BDC

Data Access Control

Row-level security to your objects in SAP BDC

Data Access Controls enable row-level security by controlling which data users can access.

When applied to a data layer view or business layer object, access is dynamically filtered based on predefined security criteria.

The foundation of this approach is the Permission Table/View — it stores the access rules and restriction criteria that determine what data each user can see.

Key Question:

How do we effectively maintain and manage the records in permission tables/views to ensure accurate and governed data access?

Strategies to Populate Permission Tables

Three paths to keep row-level authorizations current — trade-offs at a glance

Manual Maintenance

Data Builder / CSV Upload

PROS

- ✓ No integration build required
- ✓ Full manual control for one-off or ad-hoc changes
- ✓ Works even without a live source-system connection

CONS

- X Labor-intensive at scale; slow to update
- X Prone to human error and inconsistent formatting
- X No automatic link to source-of-truth ownership data

Role Synchronization

S/4HANA or SAP BW Role Sync

PROS

- ✓ Reuses existing S/4 or BW role investments
- ✓ Familiar governance model for SAP security teams
- ✓ Good fit where org already standardized on PFCG/BW roles

CONS

- X Coarser granularity — not built for row-level filters
- X Two systems to keep aligned; drift risk over time
- X Extra mapping layer needed to translate roles into restrictions
- X Not applicable for cloud-only or Non-SAP dimensions

Role name split

Haribo - Way

PROS

- ✓ No separate mapping table needed
- ✓ Leverages the approval process in GRC
- ✓ Clear visibility about data access restriction

CONS

- X Coarser granularity — not built for row-level filters (e.g. cost center authorization)
- X High dependency on perfect naming conventions
- X Another procedure for a complex rules (e.g. DEHO)

The Business Challenge

Manual, database-level row security doesn't scale with the enterprise

Slow & Error-Prone

Editing row-level permissions directly in the database is manual, hard to repeat, and easy to get wrong.

Difficult to Audit

Without a structured trail, proving who changed what — and why — becomes a compliance risk.

Central IT Bottleneck

Every new plant, region, or customer segment needs a new role, queued behind a central security team.

Fragmented Sync

Keeping SAP HANA and Datasphere authorizations aligned with source systems is a constant, brittle chore.

Authorization Governance Center

The true paths to handle row-level authorizations

Centralized, self-service governance platform that replaces complex database script queues with a guided interface to create, validate, and synchronize row-level raw-level restriction in SAP BDC

-  **Decentralized Self-Service:** Enables local business administrators to safely build and assign localized access rules (derived child roles) under template structures maintained by central IT.
-  **High-Performance Query Isolation:** Segregates permissions into stream-specific namespaced database tables. This prevents single-table database bottlenecks and isolates different access scopes (such as Sales Reporting vs. Planning).
-  **DRAGE Automation:** Auto-generates roles and maps user assignments directly from ownership fields in master data assets .
-  **Audit:** Automatic Activity Tracking Every time a role is modified, created, or assigned to an employee, the system logs the activity automatically. No spreadsheets or manual records are needed.

One Platform, Three Layers

A guided front end, a governed engine, and native replication into your SAP BDC Landscape

Application Modules

Six connected modules cover the full lifecycle, from modeling to audit

Dashboard

Health Center view of risk flags, active roles, users, and org coverage at a glance.

Organization Manager

Model the Global → Region → Plant hierarchy and map attributes to each node.

Authorization Wizard

Guided four-step flow to define, simulate, and deploy role restrictions.

Role Assignments

Assign derived roles to users and teams, with inheritance enforced automatically.

Audit Tracker

Append-only log of every create, update, and delete, with full before/after diffs.

Administration

Manage BDC connections, restriction fields, and DRAGE sync rules centrally.

What the Wizard Delivers

Four capabilities that turn row-level security into a governed, self-service process

Visualize the Org Tree

Model Global → Region → Plant hierarchies and auto-generate roles from mapped attributes.

Guided Role Wizard

A four-step flow to define restrictions, simulate access, and route for approval before deploy.

Decentralized Self-Service

Central IT owns global templates; local admins create and assign derived roles autonomously.

Automated Replication

Nested rules expand into flat rows and sync natively to SAP HANA and Datasphere.

Health Center: Know Your Risk at a Glance

The dashboard surfaces exactly where authorization risk is hiding

Critical

High-risk roles granting sensitive access

Unrestricted

Roles with no restrictions, exposing excess data

No Users

Active roles assigned to nobody

No Approver

Roles lacking a designated owner

Plus at-a-glance totals for users, active assignments, and organizational nodes across every environment.

Authorization Governance Center

Manage role-based permissions, inheritances, and organizational restrictions dynamically. Create org nodes, map custom restriction fields, and simulate data access configurations.

Central Control, Local Autonomy

Remove Central IT as the bottleneck for every regional role request

Central IT Security

- Owns Parent (Single) Roles — global, structural templates
- Holds the canManageSingleRoles permission exclusively
- Defines approved restriction fields and structural logic (e.g. "must restrict by Company Code")

Local Business Admins

- Create Derived (Child) Roles for their own region or plant
- Inherit parent restrictions automatically — read-only, cannot weaken them
- Add local parameters (e.g. Cost Center = FR01DE) and assign roles to their team, all without Central IT

Streams: Built for Scale

Namespaced tables keep millions of row-level rules fast and organized

Isolated Performance

Each stream gets its own flat table (e.g. `finance_flat_authorizations`) — small, index-friendly, fast.

Simplified Organization

Roles are grouped and filterable by business domain instead of one global list.

Targeted Data Push

Datasphere sync pushes only the relevant stream's rows, not a full enterprise bulk sync.

Context-Based Splitting

The same user can hold different access scopes for the same field across streams — e.g. broader view in Sales Reporting, narrower in Sales Planning.

A Complete, Append-Only Audit Trail

Every change to roles, restrictions, and assignments is captured and reviewable

- Filter by time range, action (Create / Update / Delete), entity type, or performer
- Isolate Critical Roles Only for high-risk review
- Drill into any entry for a full before/after diff of restriction changes

SAP BDC Authorization

Close

Why SAP BDC Authorization Wizard

- **From Weeks to Minutes**

Guided role creation and org-driven generation replace manual database edits.

- **Decentralized, Not Uncontrolled**

Local autonomy for regional teams, global governance for Central IT.

- **Audit-Ready by Design**

Append-only trail with full before/after diffs, out of the box.

- **Built to Scale**

Namespaced streams keep millions of row-level rules fast across

Let's scope a pilot for your landscape.

Next step: a working-session demo against one of your business streams.
